

Selecting Comparators in Active Surveillance Analyses

Patrick Ryan, David Madigan

31 March 2010

Background

OMOP aims to inform the appropriate use of observational healthcare data, such as administrative claims and electronic health records, for identifying and evaluating drug safety issues within an active surveillance network. To support this aim, the Partnership has assembled a research community of disparate data sources within both a centralized system and a distributed network. OMOP has also established a methods development community, where research collaborators have implemented multiple different approaches for analyzing observational data. While the specific design of each method may vary, the fundamental objective remains the same: to estimate the strength of the association between drug exposure and outcome, as a means of identifying and prioritizing drug-condition relationships that may warrant further evaluation.

As part of its empiric approach to its methodological research, OMOP is evaluating the performance of all analysis methods in their ability to identify true drug safety issues and minimize false positive findings. Each method deemed computationally feasible is being assessed for two analysis problems: Health Outcomes of Interest (HOI), and Non-Specified Associations (NSA). For both problems, 10 drugs of interest (DOI) were identified as mature products with well-characterized safety profiles. For the HOI problem, 10 outcomes were selected and one or more operational definitions were implemented for each outcome. Amongst the 10 HOIs, 9 DOI-HOI pairs represent 'true positive' safety issue test cases, 2 pairs were selected as 'true positive benefits', and 44 pairs were classified as 'negative controls'. When accounting for the multiple outcome definitions, the HOI experiment contains 35 'true positives' and 178 'negative controls', for 213 test cases in total. For the NSA problem, conditions were selected as either 'true positive' safety issues or 'negative controls' based on the status of the condition in relation to the structured product labels for the Drugs of Interest; this process resulted in a test suite that contained 599 'true positives' and 27,800 'negative controls' for 28,399 test cases in total. The rationale, process and description of the test cases is described elsewhere. Each method will be used to produce a score (eg. estimate or test statistic) for each of the test cases, and a series of measures (such as Mean Average Precision and 'precision-at-k') will be applied to those scores to assess their relative performance in classifying the status of the test cases.

All methods have user-defined parameters that allow the program to be configured to specific settings pertinent to the drug-condition relationship under study. For example, many programs allow the user to specify whether the 'time-at-risk' is defined as a constant window after drug initiation, or based on a variable period based on the length of observed exposure. Other methods allow the user to specify whether the outcome of interest is measured based on incident or prevalent occurrence.

These parameters are used to define how data is extracted and manipulated for use in analysis, and can impact the resulting estimate calculation. Largely, the degree to which these parameters influence the performance behavior of the methods is undetermined. OMOP is exploring multiple configurations of each method in an attempt to uncover patterns about which parameter settings perform best in identifying particular drug-condition associations within certain types of data.

Many methods attempt to estimate the strength of the drug-condition relationship by comparing the observed rate of drug-condition co-occurrence to an expected rate. Some methods estimate the expected rate based on a selection of one or more comparator drugs. Four methods require a user parameter for 'comparator drugs'.

- Maximized sequential probability ratio test (maxSPRT), developed by Harvard Pilgrim and Group Health Cooperative.
- Conditional sequential sampling procedure (CSSP), developed by Harvard Pilgrim and Group Health Cooperative.
- High-dimensional propensity score cohort design (hdPS), initially designed by Schneeweiss et al. and implemented by the OMOP research team.
- Incident user design (IUD), developed by Alan Brookhart of the University of North Carolina at Chapel Hill.

It is expected that the performance of these methods could be highly sensitive to the selection of the comparator drugs. This is consistent with the traditional challenge in pharmacoepidemiologic observational database study design of selecting the appropriate comparator group. The desire is to construct a comparator which is sufficiently similar to the target group that effects observed may be plausibly attributable to the exposure of interest. Analysts take great pains to define study inclusion/exclusion criteria when extracting the data and apply additional analysis techniques (such as matching, stratification, and multivariate modeling) to minimize effects of confounding and other biases. Such design decisions are pivotal to the final result, but can be resource intensive and require subjective expert opinion. As such, we propose using these methods as an opportunity to develop and evaluate alternative approaches to comparator selection.

Proposal

One research opportunity is to evaluate the performance of objective heuristics that could be used to supplement subjective decision-making. In the case of comparator selection, OMOP intends to leverage existing biomedical ontologies to construct alternative definitions of ‘comparator drugs’. NDF-RT is a drug classification system, maintained by the Department of Veteran’s Affairs. NDF-RT provides a multi-axial hierarchy for chemical ingredients in medical products (ex. ‘lisinopril’). The relationships contained within NDF-RT include: ‘may treat’ and ‘may prevent’, which enumerate indications and other potential uses of a product (ex. ‘Hypertension’); ‘mechanism of action’, often thought of a drug class (ex. ‘Angiotensin-converting Enzyme Inhibitors’); ‘chemical structure’ (ex: lisinopril); ‘Physiologic Effect’ (ex. ‘Arterial Vasodilation’). For purposes of this research, OMOP will focus on the ‘may treat’ and ‘mechanism of action’ relationships.

We propose experimenting with five alternative comparator drug definitions:

1. select all drugs with the same ‘may treat’ (indication) relationship as the DOI
2. select all drugs with the same mechanism of action (class) as the DOI
3. select all drugs within a different mechanism of action that share the same primary indication as the DOI
4. select the most prevalent drug within a different mechanism of action that shares the same primary indication as the DOI
5. Select one or more drugs based on subjective expert opinion

The first four comparator definitions can be systematically extracted from the OMOP common data model using NDF-RT. The results of applying these objective heuristics are detailed below. Note, the ‘primary indication’ requires subjective assessment of the available options when there are multiple ‘may treat’ relationships for a give product. Prevalence was estimated as proportion of people with at least one exposure, as extracted from OSCAR across all sources in the OMOP data community. The selections of drug were consistently the most prevalent in all sources. The fifth definition reflects current practice and requires subject matter expertise, including from the collaborators who developed these methods.

It should be recognized that the use of objective heuristics is prone to the same limitations as any subjective assessment involved in comparator selection. The distinction is the relationships between drugs have been pre-defined through clinical review from those who curate and maintain NDF-RT, as opposed to decided at analysis-time for a specific question of interest. As a result, relationships in NDF-RT, may not be consistent with expectations, either to differing clinical opinions or misclassification. In some instances, the classification may not be as granular as desired, and therefore the proposed heuristics may identify a broader set of comparator drugs that initially desired. The intent of conducting the research to evaluate multiple alternative comparator definitions is to allow an assessment of the acceptability of objective heuristics, as a potential supplemental approach to current practice in pharmacoepidemiologic evaluation.

Table 1 highlights the 10 OMOP drugs of Interest (DOIs), and the corresponding primary ‘may treat’ indications, ‘mechanism of action’ and ‘prevalent drugs’ selected as comparators.

DOI_DRUG_NAME	DOI_DESCRIPTION	Comparator 'May Treat' Indication	Comparator 'Mechanism of Action' class	Comparator drug (most prevalent among MoA class)
OMOP ACE Inhibitor	ACE inhibitors: benazepril, captopril, enalapril, fosinopril, lisinopril, quinapril, and ramipril; restricted to oral form	Hypertension	Angiotensin 2 Receptor Antagonists	Valsartan
OMOP Amphotericin B	parenteral Amphotericin B	Candidiasis, Chronic Mucocutaneous	14-alpha demethylase Inhibitors	Fluconazole
OMOP Antibiotics: erythromycins, sulfonamides, and tetracyclines	Antibiotics: erythromycins, sulfonamides, and tetracyclines; restricted to oral and injectable	Skin Diseases, Bacterial	Topoisomerase Inhibitors	Ciprofloxacin
OMOP Antiepileptics: carbamazepine, phenytoin	Antiepileptics: carbamazepine, phenytoin; restricted to oral and injectable	Epilepsy, Tonic-Clonic	Neurotransmitter Transporter Interactions	Pentobarbital
OMOP Benzodiazepines	Benzodiazepines: alprazolam, chlordiazepoxide, clonazepam, clorazepate, diazepam, estazolam, flurazepam, halazepam, lorazepam, oxazepam, prazepam, quazepam, temazepam, or triazolam	Anxiety Disorders	Serotonin Uptake Inhibitors	Fluoxetine
OMOP Beta blockers	Beta blockers: propanolol, metoprolol, atenolol; restricted to oral form	Heart Failure, Congestive	Angiotensin-converting Enzyme Inhibitors	Lisinopril
OMOP Bisphosphonates	Bisphosphonates: alendronate	Osteoporosis, Postmenopausal	Selective Estrogen Receptor Modulators	Raloxifene
OMOP Tricyclic antidepressants	Tricyclic antidepressants: restricted to oral and injectable	Depressive Disorder	Dopamine Uptake Inhibitors	Bupropion

DOI_DRUG_NAME	DOI_DESCRIPTION	Comparator 'May Treat' Indication	Comparator 'Mechanism of Action' class	Comparator drug (most prevalent among MoA class)
OMOP Typical antipsychotics	Typical antipsychotics: Chlorpromazine, chlorprothixene, levomepromazine, flupentixol, Fluphenazine decanoate, Fluphenazine enanthate, Fluphenazine hcl, Haloperidol, Haloperidol decanoate, Loxapine hcl, Loxapine succinate, melperon, Mesoridazine, Molindone, Perphenazine, amitriptyline hcl/perphenazine, Pimozide, pipamperone, promazine, Prochlorperazine edisylate, periciazine, Prochlorperazine maleate, Promazine, Propiomazine, Thioridazine, Thiothixene, Trifluoperazine, zuclopenthixol	Psychotic Disorders	Cholinergic Muscarinic Antagonists	olanzapine
OMOP Warfarin	Warfarin	Thromboembolism	Thrombin Inhibitors	Heparin

Comparator 1: select all drugs with the same ‘may treat’ (indication) relationship as the DOI

Table 2 highlights all ‘may treat’ relationships in NDF-RT for all medical products within the 10 DOIs. Those highlighted in yellow were designated as ‘primary indication’.

Comparator 2: select all drugs with the same mechanism of action (class) as the DOI

Table 4 highlights the mechanism of actions for the OMOP DOIs. The row highlighted in red was excluded for further analysis because it represents a broad ‘catch all’ mechanism of action.

DOI_CONCEPT_NAME	MOA_CONCEPT_NAME
OMOP ACE Inhibitor	Angiotensin-converting Enzyme Inhibitors
OMOP Amphotericin B	Ergosterol Synthesis Inhibitors
OMOP Antibiotics: erythromycins, sulfonamides, and tetracyclines	Protein Synthesis Inhibitors
OMOP Antibiotics: erythromycins, sulfonamides, and tetracyclines	Para-Aminobenzoic Acid Inhibitor
OMOP Antiepileptics: carbamazepine, phenytoin	Sodium Channel Interactions
OMOP Antiepileptics: carbamazepine, phenytoin	Unknown Cellular or Molecular Interaction
OMOP Benzodiazepines	GABA A Modulators
OMOP Beta blockers	Adrenergic beta2-Antagonists
